

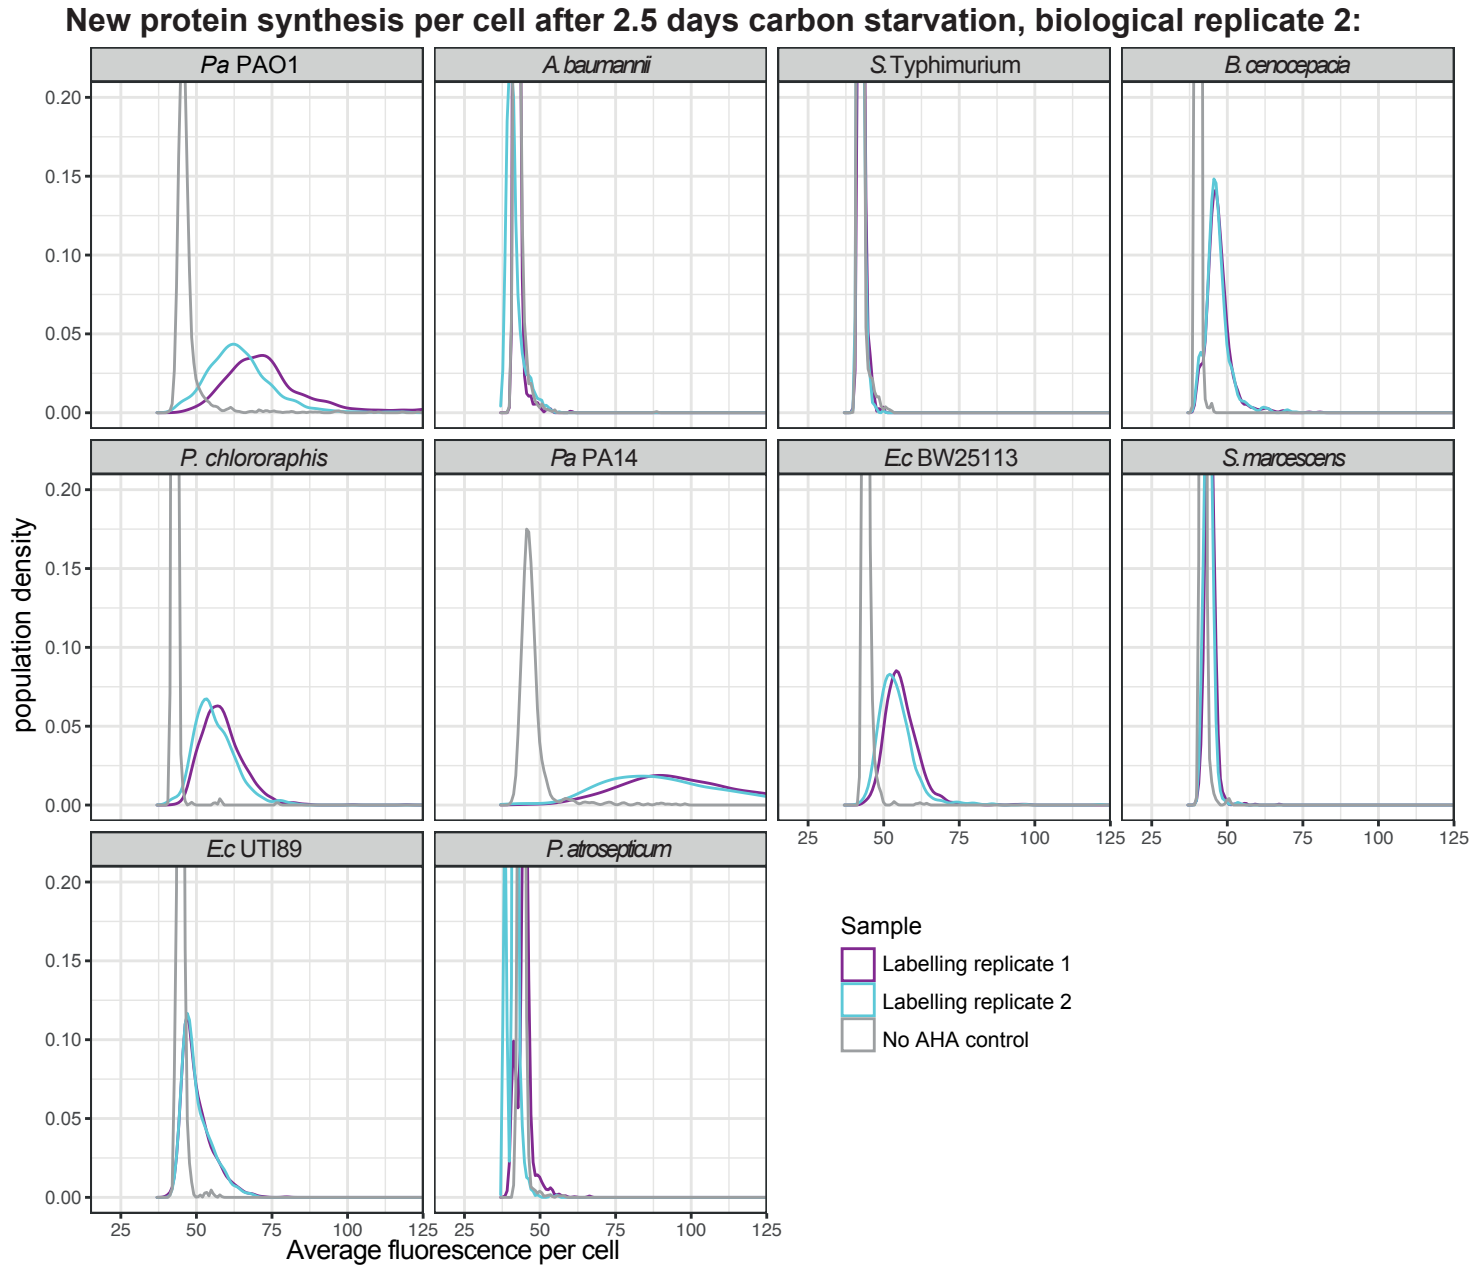

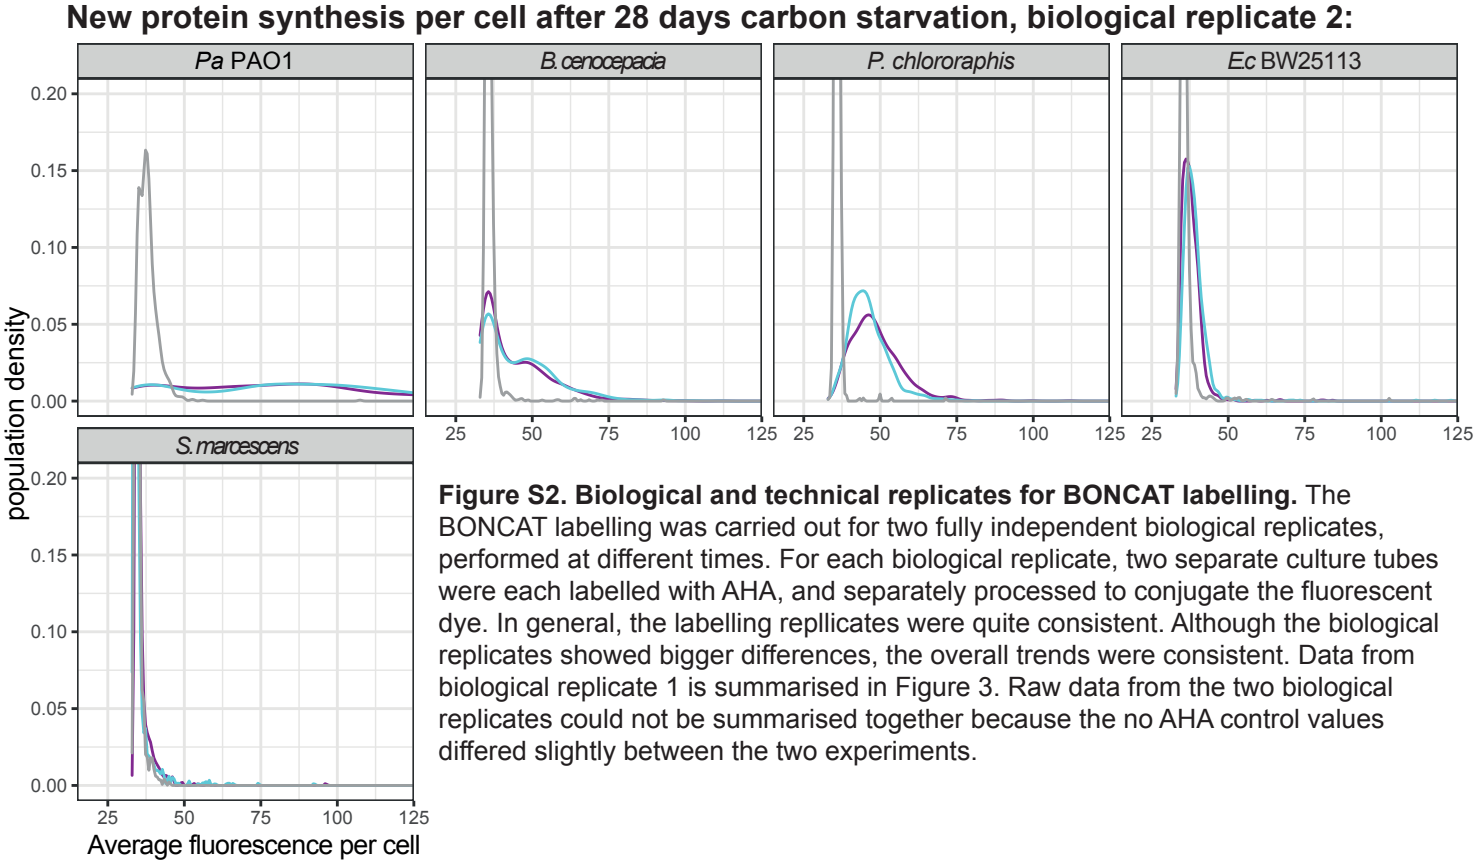

Figure S2. Biological and technical replicates for BONCAT labelling. The BONCAT labelling was carried out for two fully independent biological replicates, performed at different times. For each biological replicate, two separate culture tubes were each labelled with AHA, and separately processed to conjugate the fluorescent dye. In general, the labelling repllicates were quite consistent. Although the biological replicates showed bigger differences, the overall trends were consistent. Data from biological replicate 1 is summarised in Figure 3. Raw data from the two biological replicates could not be summarised together because the no AHA control values differed slightly between the two experiments.
