32 Materials and Methods

33 Animals and exercise program

34 Female C57BL/6 wild-type (WT) and apolipoprotein E knock-out, on a C57BL/6 35 background, (ApoE^{-/-}) mice were purchased from Charles River (Sulzfeld, Germany) 36 and kept and bred under specific pathogen-free conditions at the Central Laboratory 37 Animal Facility at the Medical University of Innsbruck on a 12-hour light/dark cycle 38 with water and food ad libitum. The mice were put on a treadmill (Columbus 39 Instruments, Columbus, OH, USA) exercise program at the age of 14 weeks (young) or 40 49-52 weeks (aged), which lasted for 5 weeks. The standard conventional chow diet 41 (CD) was simultaneously changed to a high-cholesterol (21.2% fat) Western diet (WD) 42 (Sniff GmbH, Soest, Germany) at the beginning of the experiment. 6 mice per group 43 were used and control groups were sedentary mice on CD or WD. Two methods of 44 calculation of sample size were used. To test the null hypothesis that plaque 45 regression is estimated in 90% of exercised- and 10% of not exercised-mice, we used 46 a software available online (<u>http://clincalc.com/stats/samplesize.aspx</u>). According to 47 that, the software predicted that -at least- a sample size of 10 mice (5 mice/group) 48 will have 80% power to detect a significant difference of atherosclerotic plaque 49 reduction in exercised group in comparison with not exercised mice, using a two group 50 t-test with a 0.05 two-sided significance level. Moreover, we also used a second 51 method, called "resource equation method" and according to that, 6 mice for 4 groups 52 could be considered as appropriate sample size [1]. The exercise program consisted 53 of 1 hour of running at a speed of 16 meters per minute at a 5° uphill angle, for 5 days 54 per week for 5 consecutive weeks (See Supplemental Video). The exercise program 55 was designed based on previous studies showing reduced plaque formation and 56 improved plaque stability after a 5-week treadmill intervention [2, 3]. 2 days after the 57 last training, the mice were weighed and sacrificed by terminal CO2 inhalation and 58 with cervical dislocation. Blood, aorta, axillary, brachial and inguinal lymph nodes and 59 the anterior tibialis muscles were collected for further processing. Animal experiments 60 were approved by the National Animal Experimentation Committee (Ethical approval 61 numbers BMWF-66.011/0099-II/10b/208 and the amendments BMWF-66.011/0115-62 II/10b/2009 and BMWF-66.011/0030-II/10b/2010).

2

63 En face plaque assessment

64 The aortae were cleaned from fat and surrounding muscle tissue, cut longitudinally 65 and stained with Sudan IV (Roth, Karlsruhe, Germany), for 15 minutes according to 66 manufacturers instructions. Aortal plaques were photographed en face with ProgRes 67 CapturePro 2.5 (JENOPTIK, Jena, Germany) with a fixed magnification and the total 68 plaque area was calculated using ImageJ (Version 1.43, NIH, USA), by manually 69 selecting the area of the total aorta and the areas where plaque was visible. The area 70 of the selected region is then measured by ImageJ and given as units of pixels. 71 Percentage of the aorta that is covered by plaque is calculated by dividing the total 72 area of the plaques with the total area of the aorta. 6 aortas per group were analyzed.

73 **T regulatory (T**_{REG}) cell flow cytometry

Lymph node cells (pooled) from each group (n=6) were and stained for T_{REGs} using the Mouse Regulatory T Cell Staining Kit #2 (eBioscience), according to manufacturer instructions, immediately after sacrification. Briefly, the cells were stained with antimouse CD4 FITC, anti-mouse CD25 PE and anti-mouse CD8 PE-Cy7 antibodies (Biolegend), followed by permeabilization and staining with anti-mouse FoxP3 APC antibody (eBioscience). Samples were acquired using a FACS Calibur (BD) and analysed with the CellQuest software (BD).

81 Enzyme linked immunosorbent assay (ELISA) for anti-HSP60 antibodies

82 and lipids

Anti-HSP60 antibodies were analyzed in plasma samples, as described previously [4],
with 6 samples per group being analyzed.

Serial dilutions of Precinorm L and Precinorm U (Roche Diagnostics, Indianapolis, IN, USA) of standards for the cholesterol and triglycerides, respectively, were prepared. Standards and plasma samples were mixed with Chol-Reagent (Roche) and incubated for 10 minutes. The samples were measured at OD₄₅₉ using the PowerWave XS (Bio-Tek, Winooski, VT, USA) and the results were analyzed with KC Junor Software (Bio-Tek). 6 samples per group were analyzed.

91 Luminex cytokine measurements

92

93 Luminex panels for interleukin (IL)-1β, IL-6, IL-10, IL-17, interferon (IFN)-γ, tumor 94 necrosis factor (TNF)- α and transforming growth factor (TGF)- β 1 (Bio-Rad, München, 95 Germany) were used to measure plasma cytokine levels according to manufacturers 96 instructions. Briefly, the plasma samples were added in duplicates, and bead 97 standards were added in four-fold serial dilutions on 96-well filter plates. Thereafter, 98 the samples were incubated with a detection antibody followed by streptavidin-PE. 99 After washing, the samples were measured on the Bio-Plex 200 System (Bio-Rad). 3 100 samples per group were analyzed. Results are presented as pg/ml.

101 **RNA isolation and cDNA preparation**

102 Total RNA was extracted from the tibialis anterior muscles from 3 mice per group 103 following the double extraction protocol: RNA isolation by acid guanidinium 104 thiocyanate-phenol-chlorofrom extraction (Trizol, Invitrogen) followed by a RNeasy 105 clean-up procedure (Qiagen). RNA concentration and purity were assessed in a 106 spectrophotometer (Nanodrop) and A_{260/280} and A_{260/230} ratios were determined. The 107 integrity of the RNA was assessed by the Agilent Bioanalyzer (Agilent Technologies). 108 For the reverse transcription reaction, 0.1µg of total RNA for each sample was used, 109 using the WT expression kit (Ambion) starting with the T7 promoter-tailed random 110 hexamers. cRNA was synthesized using a T7 polymerase catalyzed reaction containing 111 unmodified ribonucleoside triphosphates. Single cDNA was synthesized from the 112 cRNA template using random primers and dNTPs. The cRNA was hydrolyzed by RNase 113 H and the single-stranded cDNA was purified. Fragmentation of the single-stranded 114 cDNA was done with endonuclease I at uracil-containing positions. The fragmented 115 cDNA is end-labeled with a biotinylated nucleotide analog.

116 Microarray expression profiling

Three independent microarray analyses were preformed for each group of samples. Total RNA was processed for the use on mouse GeneChip[®] Gene 1.1 ST Array Strip (Affymetrix, Santa Clara, CA, USA) containing 700.000 murine probe sets which interrogates 29.000 transcripts. Sequences used in the design of the array were selected from GenBank[®], dbEST and RefSeq. The fragmented cDNA was added to a hybridization solution and incubated to a microarray chip overnight at 45°C. The chips were then transferred to a fluidics instrument to wash away unhybridized cDNA.
Bound cDNA was then labeled with phycoerythrin-conjugated streptavidin (SAPE).
Additional flours were then added using a biotinylated anti-streptavidin antibody and
additional SAPE. The chip fluorescence was then measured using confocal laser
scanning and the images were analyzed using the Affymetrix GCOD software version
1.4.

129 Analysis of microarray data

130 Microarray data were analyzed using the R/Bioconductor statistical software 131 environment [5]. Preprocessing and quantile normalization were done by the robust 132 multi-array average method (RMA) [6]. Probesets were annotated following a recent 133 Affymetrix annotation file and only probesets with mRNA Refseq annotation were 134 considered. Differentially expressed genes (DEG) were identified by using linear 135 models and the empirical Bayes methods in the package *limma* [7] and p-values were 136 adjusted for multiple testing based on the false discovery rate according to the 137 Benjamini-Hochberg method [8]. All of the 48 possible individual comparisons (4 138 factors age, genotype, exercise, diet with 2 levels each) were done and two-way 139 analyses (exercise x diet) were performed on the 4 experimental conditions young/wt, 140 young/ApoE^{-/-}, old/wt, old/ApoE^{-/-}. Genes were considered differentially expressed 141 with adjusted P-values <0.05 and >1.3 fold change (or where stated>2 fold change). 142 Gene ontology (GO) and pathway analyses for differentially expressed genes were 143 performed using DAVID [9, 10]. Hierarchical clustering and heat map visualization 144 were done using Genesis [11]. Accession number: E-MTAB-5685.

145

146 **Quantitative RT-PCR (qPCR)**

The qPCR reactions were performed using the SsoAdvanced[™] Universal SYBR[®] Green Supermix kit (Biorad, Germany) in a CFX96 (Biorad, Germany) using following protocol: 95°C for 2 min, 40 cycles of 95°C (15s), 60°C (15s), and 72°C (10s). Gene expression was determined by using the Bio-Rad CFX Manager 3.1 software and CT values were normalized to the expression of the Hypoxanthin-Guanin-Phosphoribosyltransferase gene (HPRT). Referenced and newly designed primers used in this study were 153 synthesized by Microsynth Austria (Table 1) and specificity was tested by the

assessment of the melting curve. 3 mice per group were used.

156 **Table1**: Primer pairs used for mRNA determination

157 Statistics

- 158 All values are shown as mean ± SEM. One-way ANOVA test, followed by Bonferroni's
- 159 Multiple Comparison Test and two-way unpaired Student's t-test were used. P-values
- 160 <0.05 were considered as significant. The data were analysed with GraphPad Prism
- 161 version 5.0c. The analysis of microarray data was done as stated above.
